

Highchairs

5 This invention relates to highchairs.

According to the present invention there is provided a highchair in which a seat having a back-rest is carried by respective front and rear leg-supports, wherein the 10 seat, its back and the front leg-support are provided together in one by an elongate, unitary member.

The elongate member may be a one-piece moulding, and in these circumstances may be a laminate, and may have a 15 core of wood (for example, ply-wood), plastics or a material of honeycomb structure. The laminate may be faced with a wood veneer or plastics (for example, a plastics having a melamine content such as that sold under the Registered Trade Mark FORMICA).

20 The rear leg-support, which may comprise a pair of legs, may be pivoted to the elongate member so that the highchair can be collapsed with the rear leg-support folded onto the front leg-support. A stay-element which 25 is pivoted to the rear leg-support may be selectively engageable within a socket on the underside of the seat-portion of the elongate member for holding the rear leg-support extended rearwardly of the seat-portion in the erect condition of the highchair. Where the rear leg- 30 support comprises a pair of legs, the stay-element may be a tubular frame located between the legs and pivoted to them.

35 A collapsible highchair in accordance with the present invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figures 1 and 2 are, respectively, side and front elevations of the highchair according to the invention, in its erect condition; and

5 Figures 3 and 4 are perspective views of the erect highchair of Figures 1 and 2 from above and below respectively.

Referring to Figures 1 to 4, the highchair involves a
10 unitary member in the form of a one-piece, elongate
moulding 1 to which a pair of tubular-steel legs 2 are
pivoted for rearwardly-inclined support of the highchair
in its erect condition. The moulding 1 is contoured
15 along its length to define for the erect condition, a
substantially-horizontal portion 3 that forms the seat of
the chair, a substantially-upright portion 4 curved up
from the rear of the portion 2 to form a back-rest to the
seat, and a longer portion 5 curved down from the front
20 of the seat-portion 2 to provide a forwardly-inclined
front leg-support for the chair. The width of the
moulding 1 varies along its length also, narrowing down
from the top of the back-rest portion 4 to run into the
rear of the seat-portion 3, and then increasing slightly
25 towards the front of the seat-portion 3. Substantially
the same width is held from the front of the seat-portion
3 down to near the bottom of the leg-support portion 5,
where the moulding 1 splay out to form foot projections
6 for floor-contact.

30 The tubular legs 2, which are interconnected by a cross-
piece 7, are mounted on pivots 8 within respective
brackets 9 secured to either side under the seat-portion
3. They are extended rearwardly for the erect condition
35 of the highchair, by snap engagement of a stay-element in
the form of tubular-steel frame 10, within a socket 11
mounted on the underside of the seat-portion 3. In this
respect, the frame 10 is mounted on pivots 12 between the

legs 2, and the action of engaging the frame 10 with the socket 11 pivots the legs 2 rearwardly. The weight of the highchair and its occupant acts to hold the legs 2 extended in this way so as to enhance retention of the 5 frame 10 within the socket 11 and the highchair in its erect condition.

The highchair can be collapsed simply by withdrawing the frame 10 from engagement within the socket 11. This is 10 achieved by lifting the legs 2 from the floor and pushing them forward to pivot about the brackets 9. In the fully-collapsed condition, the legs 2 are folded forwards onto the underside of the portion 5, and the highchair can be re-erected from this simply by pulling the legs 2 15 rearwardly and re-engaging the frame 10 with the socket 11. A basket or other container 13 is hung within the frame 10 and can be removed for the collapsed condition, or while the highchair is in the erect condition, simply by unhitching or otherwise detaching it from the frame 20 10.

The brackets 9 used for pivoting the legs 2 to the moulding 1, also serve for the attachment of a steel tube 14 that provide arm-rests to the seat. More 25 particularly, the tube 14 has portions 15 at either end which curve upwardly from the brackets 9 to form the arm-rests either side of the seat-portion 3. The portions 15 at their upper ends, bend round the back of the back-rest portion 4 to be interconnected by a straight portion 16 30 of the tube 14 that is held to the portion 4 by brackets 17.

A forwardly-extending plastics tray 18 of the highchair is carried by a U-shape tubular-steel frame 19 which has 35 a pivotal mount 20 at each end for engaging with the tube 14. More particularly, the mounts 20 engage releasably with the tube 14 at the tops of the arm-rest portions 15

respectively, where they bend into the portion 16. In fitting the frame 19 to the chair, it is positioned straddling the front of the back-rest portion 4 with the mounts 20 projecting just beyond it on either side. The 5 frame 19 is then pulled forwards slightly to engage the mounts 20 with the tube 14 where the arm-rest portions 15 bend into the portion 16. Each mount 20 has the form of an elbow that is open on its inside (see the furthermost mount 20 represented in Figure 3) so that it 'cups' onto 10 the tube 14 around the bend. A manually-releasable catch (not shown) then becomes operative to hold it there. The frame 19, and with it the tray 18, is accordingly in this way firmly secured to the chair, but can be freed when desired, by releasing the catch and pushing the frame 19 15 slightly rearwards to disengage the mounts 20 from the tube 14.

The underside of the tray 18 has resilient-plastics 20 sockets 21 to either side for snapping onto the two arms respectively of the tubular frame 19, and a manually-releasable clip 22 for clipping onto it centrally. Furthermore, a slide-mechanism 23 under the tray 18 is operable to allow adjustment of the tray-position, 25 forwards or rearwards, relative to the frame 19; the sockets 21 are free to slide along the arms of the frame 19 as appropriate during the adjustment.

The frame 19, with or without the tray 18 attached, can be swung up from the horizontal into the substantially- 30 vertical plane of the back-rest portion 4. In this respect, frame 19 is pivoted to each mount 20, but is held fast until a sprung pin (not shown) of the mount 20 is released manually. When the pin is released, the frame 19 is freed for pivotal movement as required, for 35 example, when an infant is to sit in the chair or is to leave it.

Cushioning of the chair-seat and back-rest portions 3 and 4 for comfort of the occupant is provided by a cover 24 which also extends down from the front of the portion 3 into the portion 5 to lie under the knees of an infant 5 occupant. The cover 24 has appropriate apertures 25 and 26 (Figure 3) where attachment of harness (not shown) to the seat portion 3 is to be made for child restraint and safety.

10 The portion 5 has a series of transverse slots 27 spaced from one another at progressively-increasing distances below the seat portion 3. A plate 28 is entered in one or other of the slots 27 to provide a footrest at the appropriate height for the occupant of the chair. The 15 plate 28 engages resiliently with a plastics moulding 29 attached to the underside of the portion 5 behind the slots 21, for its retention in the respective slot 27. Adjustment of height of the footrest is made simply by pulling the plate 28 to release it from the moulding 29 and slot 27, and pushing it into another slot 27 at the 20 appropriate height, to re-engage it with the moulding 29.

The moulding 1 may be a laminate having a core of plywood or material of honeycomb structure, and external 25 skins of wood veneer or a melamine-formaldehyde methanal resin such as that sold under the Registered Trade Mark FORMICA.
